The main point of this paper can perhaps best be brought out through a comparison of the study of infancy with the study of the psycho-analytic transference. It cannot be too strongly emphasized that my statement is about infancy, and not primarily about psycho-analysis. The reason why this must be understood reaches to the root of the matter. If this paper does not contribute constructively, then it can only add to the existing confusion about the relative importance of personal and environmental influences in the development of the individual.

In psycho-analysis as we know it there is no trauma that is outside the individual's omnipotence. Everything eventually comes under ego-control, and thus becomes related to secondary processes. The patient is not helped if the analyst says: 'Your mother was not good enough … your father really seduced you … your aunt dropped you.' Changes come in an analysis when the traumatic factors enter the psycho-analytic material in the patient's own way, and within the patient's omnipotence. The interpretations that are alterative are those that can be made in terms of projection. The same applies to the benign factors, factors that led to satisfaction. Everything is interpreted in terms of the individual's love and ambivalence. The analyst is prepared to wait a long time to be in a position to do exactly this kind of work.

In infancy, however, good and bad things happen to the infant that are quite outside the infant's range. In fact infancy is the period in which the capacity for gathering external factors into the area of the infant's omnipotence is in process of formation. The ego support of the maternal care enables the infant to live and develop in spite of his being not yet able to control, or to feel responsible for, what is good and bad in the environment.

The events of these earliest stages cannot be thought of as lost through what we know as the mechanisms of repression, and therefore analysts cannot expect to find them appearing as a result of work which lessens the forces of repression. It is possible that Freud was trying to allow for these phenomena when he used the term primary repression, but this is open to argument. What is fairly certain is that the matters under discussion here have had to be taken for granted in much of the psycho-analytic literature.

Returning to psycho-analysis, I have said that the analyst is prepared to wait till the patient becomes able to present the environmental factors in terms that allow of their interpretation as projections. In the well-chosen case this result comes from the patient's capacity for confidence, which is rediscovered in the reliability of the analyst and the professional setting. Sometimes the analyst needs to wait a very long time; and in the case that is badly chosen for classical psycho-analysis it is likely that the reliability of the analyst is the most important factor (or more important than the interpretations) because the patient did not experience such reliability in the maternal care of infancy, and if the patient is to make use of such reliability he will need to find it for the first time in the analyst's behaviour. This would seem to be the basis for research into the problem of what a psycho-analyst can do in the treatment of schizophrenia and other psychoses.

In borderline cases the analyst does not always wait in vain; in the course of time the patient becomes able to make use of the psycho-analytic interpretations of the original traumata.
as projections. It may even happen that he is able to accept what is good in the environment as a projection of the simple and stable
going-on-being elements that derive from his own inherited potential.

The paradox is that what is good and bad in the infant’s environment is not in fact a projection, but in spite of this it is necessary,
if the individual infant is to develop healthily, that everything shall seem to him to be a projection. Here we find omnipotence and the
pleasure principle in operation, as they certainly are in earliest infancy; and to this observation we can add that the recognition of a
true ‘not-me’ is a matter of the intellect; it belongs to extreme sophistication and to the maturity of the individual.

In the writings of Freud most of the formulations concerning infancy derive from a study of adults in analysis. There are some
childhood observations (‘Cotton reel’ material (5)), and there is the analysis of Little Hans (3). At first sight it would seem that a great
deal of psycho-analytic theory is about early childhood and infancy, but in one sense Freud can be said to have neglected infancy as a
state. This is brought out by a footnote in ‘Formulations on the Two Principles of Mental Functioning’ (4, p. 220) in which he shows
that he knows he is taking for granted the very things that are under discussion in this paper. In the text he traces the development
from the pleasure-principle to the reality-principle, following his usual course of reconstructing the infancy of his adult patients. The
note runs as follows:

It will rightly be objected that an organization which was a slave to the pleasure principle and neglected the reality of the
external world could not maintain itself alive for the shortest time, so that it could not have come into existence at all. The
employment of a fiction like this is, however, justified when one considers that the infant—provided one includes with it the
care it receives from its mother—does almost realize a psychical system of this kind.

Here Freud paid full tribute to the function of maternal care, and it must be assumed that he left this subject alone only because he
was not ready to discuss its implications. The note continues:

It probably hallucinates the fulfilment of its internal needs; it betrays its unpleasure, when there is an increase of stimulus
and an absence of satisfaction, by the motor discharge of screaming and beating about with its arms and legs, and it then
experiences the satisfaction it has hallucinated. Later, as an older child, it learns to employ these manifestations of discharge
intentionally as methods of expressing its feelings. Since the later care of children is modelled on the care of infants, the
dominance of the pleasure principle can really come to an end only when a child has achieved complete psychical
detachment from its parents.

The words: ‘provided one includes with it the care it receives from its mother’ have great importance in the context of this study.
The infant and the maternal care together form a unit. Certainly if one is to study the theory of the parent-infant relationship one must
come to a decision about these matters, which concern the real meaning of the world dependence. It is not enough that it is
acknowledged that the environment is important. If there is to be a discussion of the theory of the parent-infant relationship, then we
are divided into two if there are some who do not allow that at the earliest stages the infant and the maternal care belong to each other
and cannot be disentangled. These two things, the infant and the maternal care, disentangle and dissociate themselves in health; and
health, which means so many things, to some extent means a disentanglement of maternal care from something which we then call the
infant or the beginnings of a growing child. This idea is covered by Freud's words at the end of the footnote: ‘the dominance of the
pleasure principle can really come to an end only when a child has achieved complete psychical detachment from its parents’. (The
middle part of this footnote will be discussed in a later section, where it will be suggested that Freud's words here are inadequate and
misleading in certain respects, if taken to refer to the earliest stage.)

The Word 'Infant'

In this paper the word infant will be taken to refer to the very young child. It is necessary to say this because in Freud's writings
the word sometimes seems to include the child up to the age of the passing of the Oedipus complex. Actually the word infant implies
'not talking'

4 I once said: ‘There is no such thing as an infant’, meaning, of course, that whenever one finds an infant one finds maternal care, and without
maternal care there would be no infant. (Discussion at a Scientific Meeting of the British Psycho-Analytical Society, circa 1940). Was, I influenced,
without knowing it, by this footnote of Freud's?

and his working with it in the transference.8

It would seem that the study of ego defences takes the investigator back to pregenital id-manifestations, whereas the study of ego psychology takes him back to dependence, to the maternal-care–infant unit.

One half of the theory of the parent-infant relationship concerns the infant, and is the theory of the infant's journey from absolute dependence, through relative dependence, to independence, and, in parallel, the infant's journey from the pleasure principle to the reality principle, and from autoerotism to object relationships. The other half of the theory of the parent-infant relationship concerns maternal care, that is to say the qualities and changes in the mother that meet the specific and developing needs of the infant towards whom she orients.

A. THE INFANT

The key word in this part of the study is dependence. Human infants cannot start to be except under certain conditions. These conditions are studied below, but they are part of the psychology of the infant. Infants come into being differently according to whether the conditions are favourable or unfavourable. At the same time conditions do not determine the infant's potential. This is inherited, and it is legitimate to study this inherited potential of the individual as a separate issue, provided always that it is accepted that the inherited potential of an infant cannot become an infant unless linked to maternal care.

The inherited potential includes a tendency towards growth and development. All stages of emotional growth can be roughly dated. Presumably all developmental stages have a date in each individual child. Nevertheless, not only do these dates vary from child to child, but also, even if they were known in advance in the case of a given child, they could not be used in predicting the child's actual development because of the other factor, maternal care. If such dates could be used in prediction at all, it would be on the basis of assuming a maternal care that is adequate in the important respects. (This obviously does not mean adequate only in the physical sense; the meaning of adequacy and inadequacy in this context is discussed below.)

The Inherited Potential and Its Fate

It is necessary here to attempt to state briefly what happens to the inherited potential if this is to develop into an infant, and thereafter into a child, a child reaching towards independent existence. Because of the complexities of the subject such a statement must be made on the assumption of satisfactory maternal care, which means parental care. Satisfactory parental care can be classified roughly into three overlapping stages:

a. Holding.

b. Mother and infant living together. Here the father's function (of dealing with the environment for the mother) is not known to the infant.

c. Father, mother, and infant, all three living together.

The term 'holding' is used here to denote not only the actual physical holding of the infant, but also the total environmental provision prior to the concept of living with. In other words, it refers to a three-dimensional or space relationship with time gradually added. This overlaps with, but is initiated prior to, instinctual experiences that in time would determine object relationships. It includes the management of experiences that are inherent in existence, such as the completion (and therefore the non-completion) of processes, processes which from the outside may seem to be purely physiological but which belong to infant psychology and take place in a complex psychological field, determined by the awareness and the empathy of the mother. (This concept of holding is further discussed below.)

The term 'living with' implies object relationships, and the emergence of the infant from the state of being merged with the mother, or his perception of objects as external to the self.

This study is especially concerned with the 'holding' stage of maternal care, and with the

8 For a clinical example see (17).

Infant Development During the Holding Phase

complex events in infant's psychological development that are related to this holding phase. It should be remembered, however, that a division of one phase from another is artificial, and merely a matter of convenience, adopted for the purpose of clearer definition.
In the light of this some characteristics of infant development during this phase can be enumerated. It is at this stage that
primary process
primary identification
auto-erotism
primary narcissism
are living realities.

In this phase the ego changes over from an unstructured state to a more integrated state, and so the infant becomes able to experience anxiety associated with disintegration. The word disintegration begins to have a meaning which it did not possess before this stage. In healthy development at this stage the infant retains the capacity for re-experiencing unstructured states, but this depends on the continuation of reliable maternal care or on the build-up in the infant of memories of maternal care beginning gradually to be perceived as such. The result of healthy progress in the infant's development during this stage is that he attains to what might be called 'unit status'. The infant becomes a person, an individual in his own right.

Associated with this attainment is the infant's psychosomatic existence, which begins to take on a personal pattern; I have referred to this as the psyche indwelling in the soma. The basis for this indwelling is a linkage of motor and sensory experiences with the infant's new state of being a person. As a further development there comes into existence what might be called a limiting membrane, which to some extent (in health) is equated with the surface of the skin, and has a position between the infant's 'me' and his 'not-me'. So the infant comes to have an inside and an outside, and a body-scheme. In this way meaning comes to the function of intake and output; moreover, it gradually becomes meaningful to postulate a personal or inner psychic reality for the infant.

During the holding phase other processes are initiated; the most important is the dawn of intelligence and the beginning of a mind as something distinct from the psyche. From this follows the whole story of the secondary processes and of symbolic functioning, and of the organization of a personal psychic content, which forms a basis for dreaming and for living relationships.

At the same time there starts in the infant a joining up of two roots of impulsive behaviour. The term 'fusion' indicates the positive process whereby diffuse elements that belong to movement and to muscle erotism become (in health) fused with the orgiastic functioning of the erogenous zones. This concept is more familiar as the reverse process of defusion, which is a complicated defence in which aggression becomes separated out from erotic experience after a period in which a degree of fusion has been achieved. All these developments belong to the environmental condition of holding, and without a good enough holding these stages cannot be attained, or once attained cannot become established.

A further development is in the capacity for object relationships. Here the infant changes from a relationship to a subjectively conceived object to a relationship to an object objectively perceived. This change is closely bound up with the infant's change from being merged with the mother to being separate from her, or to relating to her as separate and 'not-me'. This development is not specifically related to the holding, but is related to the phase of 'living with'…

### Dependence

In the holding phase the infant is maximally dependent. One can classify dependence thus:

i. **Absolute Dependence.** In this state the infant has no means of knowing about the maternal care, which is largely a matter of prophylaxis. He cannot gain control over what is well and what is badly done, but is only in a position to gain profit or to suffer disturbance.

ii. **Relative Dependence.** Here the infant can become aware of the need for the details of maternal care, and can to a growing extent relate them to personal impulse, and then later, in a psycho-analytic treatment, can reproduce them in the transference.

---

9 For an earlier statement by me on this issue see (13).
10 Here the work on primitive fantasy, with whose richness and complexity we are familiar through the teachings of Melanie Klein, becomes applicable and appropriate.

**WARNING!** This text is printed for the personal use of the subscriber to PEP Web and is copyright to the Journal in which it originally appeared. It is illegal to copy, distribute or circulate it in any form whatsoever.

- 590 -

iii. **Towards Independence.** The infant develops means for doing without actual care. This is accomplished through the accumulation of memories of care, the projection of personal needs and the introjection of care details, with the
development of confidence in the environment. Here must be added the element of intellectual understanding with its tremendous implications.

**Isolation of the Individual**

Another phenomenon that needs consideration at this phase is the hiding of the core of the personality. Let us examine the concept of a central or true self. The central self could be said to be the inherited potential which is experiencing a continuity of being, and acquiring in its own way and at its own speed a personal psychic reality and a personal body scheme. It seems necessary to allow for the concept of the isolation of this central self as a characteristic of health. Any threat to this isolation of the true self constitutes a major anxiety at this early stage, and defences of earliest infancy appear in relation to failures on the part of the mother (or in maternal care) to ward off impingements which might disturb this isolation.

Impingements may be met and dealt with by the ego organization, gathered into the infant's omnipotence and sensed as projections. On the other hand they may get through this defence in spite of the ego support which maternal care provides. Then the central core of the ego is affected, and this is the very nature of psychotic anxiety. In health the individual soon becomes invulnerable in this respect, and if external factors impinge there is merely a new degree and quality in the hiding of the central self. In this respect the best defence is the organization of a false self. Instinctual satisfactions and object relationships themselves constitute a threat to the individual's personal going-on-being. Example: a baby is feeding at the breast and obtains satisfaction. This fact by itself does not indicate whether he is having an ego-syntonic id experience or, on the contrary, is suffering the trauma of a seduction, a threat to personal ego continuity, a threat by an id experience which is not ego-syntonic, and with which the ego is not equipped to deal.

In health object relationships can be developed on the basis of a compromise, one which involves the individual in what later would be called cheating and dishonesty, whereas a direct relationship is possible only on the basis of regression to a state of being merged with the mother.

**Annihilation**

Anxiety in these early stages of the parent-infant relationship relates to the threat of annihilation, and it is necessary to explain what is meant by this term.

In this phase which is characterized by the essential existence of a holding environment, the 'inherited potential' is becoming itself a 'continuity of being'. The alternative to being is reacting, and reacting interrupts being and annihilates. Being and annihilation are the two alternatives. The holding environment therefore has as its main function the reduction to a minimum of impingements to which the infant must react with resultant annihilation of personal being. Under favourable conditions the infant establishes a continuity of existence and then begins to develop the sophistications which make it possible for impingements to be gathered into the area of omnipotence. At this stage the word death has no possible application, and this makes the term death instinct unacceptable in describing the root of destructiveness. Death has no meaning until the arrival of hate and of the concept of the whole human person. When a whole human person can be hated, death has meaning, and close on this follows that which can be called maiming; the whole hated and loved person is kept alive by being castrated or otherwise maimed instead of killed. These ideas belong to a phase later than that characterized by dependence on the holding environment.

**Freud's Footnote Re-examined**

At this point it is necessary to look again at Freud's statement quoted earlier. He writes: 'Probably it (the baby) hallucinates the fulfilment of its inner needs; it betrays its pain due to increase of stimulation and delay of satisfaction by the motor discharge of crying and struggling, and then experiences the hallucinated satisfaction.' The theory indicated in this part of the statement fails to cover the requirements of the earliest phase. Already by these words reference is being made to object relationships, and the validity of this part of Freud's statement depends on his taking for granted the earlier aspects of maternal care, those which are here described as belonging to the holding phase. On the other hand, this sentence of Freud fits exactly the requirements in the next phase, that which is characterized by a relationship between infant and mother in which object relationships and instinctual or
erotogenic-zone satisfactions hold sway; that is, when development proceeds well.

**B. THE ROLE OF THE MATERNAL CARE**

I shall now attempt to describe some aspects of maternal care, and especially holding. In this paper the concept of holding is important, and a further development of the idea is necessary. The word is here used to introduce a full development of the theme contained in Freud's phrase '… when one considers that the infant—provided one includes with it the care it receives from its mother—does almost realize a psychical system of this kind.' I refer to the actual state of the infant-mother relationship at the beginning when the infant has not separated out a self from the maternal care on which there exists absolute dependence in a psychological sense.14

At this stage the infant needs and in fact usually gets an environmental provision which has certain characteristics:

- It meets physiological needs. Here physiology and psychology have not yet become distinct, or are only in the process of doing so; and
- It is reliable. But the environmental provision is not mechanically so. It is reliable in a way that implies the mother's empathy.

**Holding**

- Protects from physiological insult. Takes account of the infant's skin sensitivity—touch, temperature, auditory sensitivity, visual sensitivity, sensitivity to falling (action of gravity) and of the infant's lack of knowledge of the existence of anything other than the self.
- It includes the whole routine of care throughout the day and night, and it is not the same with any two infants because it is part of the infant, and no two infants are alike.
- Also it follows the minute day-to-day changes belonging to the infant's growth and development, both physical and psychological.

It should be noted that mothers who have it in them to provide good enough care can be enabled to do better by being cared for themselves in a way that acknowledges the essential nature of their task. Mothers who do not have it in them to provide good enough care cannot be made good enough by mere instruction.

Holding includes especially the physical holding of the infant, which is a form of loving. It is perhaps the only way in which a mother can show the infant her love of it. There are those who can hold an infant and those who cannot; the latter quickly produce in the infant a sense of insecurity, and distressed crying.

All this leads right up to, includes, and co-exists with the establishment of the infant's first object relationships and his first experiences of instinctual gratification.15

It would be wrong to put the instinctual gratification (feeding etc.) or object relationships (relation to the breast) before the matter of ego organization (i.e. infant ego reinforced by maternal ego). The basis for instinctual satisfaction and for object relationships is the handling and the general management and the care of the infant, which is only too easily taken for granted when all goes well.

The mental health of the individual, in the sense of freedom from psychosis or liability to psychosis (schizophrenia), is laid down by this maternal care, which when it goes well is scarcely noticed, and is a continuation of the physiological provision that characterizes the prenatal state. This environmental provision is also a continuation of the tissue aliveness and the functional health which (for the infant) provides silent but vitally important ego support. In this way schizophrenia or infantile psychosis or a liability to psychosis at a later date is related to a failure of environmental provision. This is not to say, however, that the ill effects of such failure cannot be described in terms of ego distortion and of the defences against primitive

---

14 Reminder: to be sure of separating this off from object-relationships and instinct-gratification I must artificially confine my attention to the body needs of a general kind. A patient said to me: 'A good analytic hour in which the right interpretation is given at the right time is a good feed'.

15 For further discussion of this aspect of the developmental processes see my paper (14).

---

anxieties, that is to say in terms of the individual. It will be seen, therefore, that the work of Klein on the splitting defence mechanisms and on projections and introjections and so on, is an attempt to state the effects of failure of environmental provision in terms of the individual. This work on primitive mechanisms gives the clue to only one part of the story, and a reconstruction of the environment and of its failures provides the other part. This other part cannot appear in the transference because of the patient's lack of knowledge of the maternal care, either in its good or in its failing aspects, as it existed in the original infantile setting.
Examination of One Detail of Maternal Care

I will give an example to illustrate subtlety in infant care. An infant is merged with the mother, and while this remains true the nearer the mother can come to an exact understanding of the infant's needs the better. A change, however, comes with the end of merging, and this end is not necessarily gradual. As soon as mother and infant are separate, from the infant's point of view, then it will be noted that the mother tends to change in her attitude. It is as if she now realizes that the infant no longer expects the condition in which there is an almost magical understanding of need. The mother seems to know that the infant has a new capacity, that of giving a signal so that she can be guided towards meeting the infant's needs. It could be said that if now she knows too well what the infant needs, this is magic and forms no basis for an object relationship. Here we get to Freud's words: 'It (the infant) probably hallucinates the fulfillment of its internal needs; it betrays its unpleasure, when there is an increase of stimulus and an absence of satisfaction, by the motor discharge of screaming and beating about with its arms and legs, and it then experiences the satisfaction it has hallucinated.' In other words, at the end of merging, when the child has become separate from the environment, an important feature is that the infant has to give a signal.16 We find this subtlety appearing clearly in the transference in our analytic work. It is very important, except when the patient is regressed to earliest infancy and to a state of merging, that the analyst shall not know the answers except in so far as the patient gives the clues. The analyst gathers the clues and makes the interpretations, and it often happens that patients fail to give the clues, making certain thereby that the analyst can do nothing. This limitation of the analyst's power is important to the patient, just as the analyst's power is important, represented by the interpretation that is right and that is made at the right moment, and that is based on the clues and the unconscious co-operation of the patient who is supplying the material which builds up and justifies the interpretation. In this way the student analyst sometimes does better analysis than he will do in a few years' time when he knows more. When he has had several patients he begins to find it irksome to go as slowly as the patient is going, and he begins to make interpretations based not on material supplied on that particular day by the patient but on his own accumulated knowledge or his adherence for the time being to a particular group of ideas. This is of no use to the patient. The analyst may appear to be very clever, and the patient may express admiration, but in the end the correct interpretation is a trauma, which the patient has to reject, because it is not his. He complains that the analyst attempts to hypnotize him, that is to say, that the analyst is inviting a severe regression to dependence, pulling the patient back to a merging in with the analyst.

The same thing can be observed with the mothers of infants; mothers who have had several children begin to be so good at the technique of mothering that they do all the right things at the right moments, and then the infant who has begun to become separate from the mother has no means of gaining control of all the good things that are going on. The creative gesture, the cry, the protest, all the little signs that are supposed to produce what the mother does, all these things are missing, because the mother has already met the need just as if the infant were still merged with her and she with the infant. In this way the mother, by being a seemingly good mother, does something worse than castrate the infant. The latter is left with two alternatives; either being in a permanent state of regression and of being merged with the mother, or else staging a total rejection of the mother, even of the seemingly good mother.

We see therefore that in infancy and in the management of infants there is a very subtle distinction between the mother's understanding of her infant's need based on empathy, and her change over to an understanding based on

16 Freud's later theory of anxiety as a signal to the ego (6).

Unawareness of Satisfactory Maternal Care

It is axiomatic in these matters of maternal care of the holding variety that when things go well the infant has no means of knowing what is being properly provided and what is being prevented. On the other hand it is when things do not go well that the infant becomes aware, not of the failure of maternal care, but of the results, whatever they may be, of that failure; that is to say, the infant becomes aware of reacting to some impingement. As a result of success in maternal care there is built up in the infant a continuity of being which is the basis of ego strength; whereas the result of each failure in maternal care is that the continuity of being
is interrupted by reactions to the consequences of that failure, with resultant ego-weakening. Such interruptions constitute annihilation, and are evidently associated with pain of psychotic quality and intensity. In the extreme case the infant exists only on the basis of a continuity of reactions to impingement and of recoveries from such reactions. This is in great contrast to the continuity of being which is my conception of ego strength.

C. THE CHANGES IN THE MOTHER

It is important in this context to examine the changes that occur in women who are about to have a baby or who have just had one. These changes are at first almost physiological, and they start with the physical holding of the baby in the womb. Something would be missing, however, if a phrase such as 'maternal instinct' were used in description. The fact is that in health women change in their orientation to themselves and to the world, but however deeply rooted in physiology such changes may be, they can be distorted by mental ill-health in the woman. It is necessary to think of these changes in psychological terms and this in spite of the fact that there may be endocrinological factors which can be affected by medication.

No doubt the physiological changes sensitize the woman to the more subtle psychological changes that follow.

Soon after conception, or when conception is known to be possible, the woman begins to alter in her orientation, and to be concerned with the changes that are taking place within her. In various ways she is encouraged by her own body to be interested in herself. The mother shifts some of her sense of self on to the baby that is growing within her. The important thing is that there comes into existence a state of affairs that merits description and the theory of which needs to be worked out.

The analyst who is meeting the needs of a patient who is reliving these very early stages in the transference undergoes similar changes of orientation; and the analyst, unlike the mother, needs to be aware of the sensitivity which develops in him or her in response to the patient's immaturity and dependence. This could be thought of as an extension of Freud's description of the analyst as being in a voluntary state of attentiveness.

A detailed description of the changes in orientation in a woman who is becoming or who has just become a mother would be out of place here, and I have made an attempt elsewhere to describe these changes in popular or non-technical language (23).

There is a psychopathology of these changes in orientation, and the extremes of abnormality are the concern of those who study the psychology of puerperal insanity. No doubt there are many variations in quality which do not constitute abnormality. It is the degree of distortion that constitutes abnormality.

By and large mothers do in one way or another identify themselves with the baby that is growing within them, and in this way they achieve a very powerful sense of what the baby needs. This is a projective identification. This identification with the baby lasts for a certain length of time after parturition, and then gradually loses significance.

In the ordinary case the mother's special orientation to the infant carries over beyond the birth process. The mother who is not distorted in these matters is ready to let go of her identification with the infant as the infant needs to become separate. It is possible to provide good initial care, but to fail to complete the process through an inability to let it come to an end, so that the mother tends to remain merged with her infant and to delay the infant's separation from her. It is in any case a difficult thing for a mother to separate from her infant at the same speed at which the infant needs to become separate from her.

The important thing, in my view, is that the mother through identification of herself with her infant knows what the infant feels like and so is able to provide almost exactly what the infant needs in the way of holding and in the provision of an environment generally. Without such an identification I consider that she is not able to provide what the infant needs at the beginning, which is a live adaptation to the infant's needs. The main thing is the physical holding, and this is the basis of all the more complex aspects of holding, and of environmental provision in general.

It is true that a mother may have a baby who is very different from herself so that she miscalculates. The baby may be quicker or slower than she is, and so on. In this way there may be times when what she feels the baby needs is not in fact correct. However, it...
seems to be usual that mothers who are not distorted by ill-health or by present-day environmental stress do tend on the whole to know what their infants need accurately enough, and further, they like to provide what is needed. This is the essence of maternal care.

With 'the care that it receives from its mother' each infant is able to have a personal existence, and so begins to build up what might be called a continuity of being. On the basis of this continuity of being the inherited potential gradually develops into an individual infant. If maternal care is not good enough then the infant does not really come into existence, since there is no continuity of being; instead the personality becomes built on the basis of reactions to environmental impingement.

All this has significance for the analyst. Indeed it is not from direct observation of infants so much as from the study of the transference in the analytic setting that it is possible to gain a clear view of what takes place in infancy itself. This work on infantile dependence derives from the study of the transference and counter-transference phenomena that belong to the psycho-analyst's involvement with the borderline case. In my opinion this involvement is a legitimate extension of psycho-analysis, the only real alteration being in the diagnosis of the illness of the patient, the etiology of whose illness goes back behind the Oedipus complex, and involves a distortion at the time of absolute dependence.

Freud was able to discover infantile sexuality in a new way because he reconstructed it from his analytic work with psycho-neurotic patients. In extending his work to cover the treatment of the borderline psychotic patient it is possible for us to reconstruct the dynamics of infancy and of infantile dependence, and of the maternal care that meets this dependence.

**SUMMARY**

i. An examination is made of infancy; this is not the same as an examination of primitive mental mechanisms.

ii. The main feature of infancy is dependence; this is discussed in terms of the holding environment.

iii. Any study of infancy must be divided into two parts:
   a. Infant development facilitated by good-enough maternal care;
   b. Infant development distorted by maternal care that is not good enough.

iv. The infant ego can be said to be weak, but in fact is strong because of the ego support of maternal care. Where maternal care fails the weakness of the infant ego becomes apparent.

v. Processes in the mother (and in the father) bring about, in health, a special state in which the parent is orientated to the infant, and is thus in a position to meet the infant's dependence. There is a pathology of these processes.

vi. Attention is drawn to the various ways in which these conditions inherent in what is here termed the holding environment can or cannot appear in the transference if at a later date the infant should come into analysis.
